Marijuana is SAFER
By Steve Fox, Paul Armentano, Mason Tvert, Chelsea Green, White River Junction, VT, 2009. 209 pp., $14.95.

A grapevine and a cannabis plant are depicted side-by-side on a box-label from a ruined Roman temple at Baalbek in Lebanon’s fertile Bekka Valley. One of the world’s sweet spots for growing cannabis, this region is also known for its fine wines. It is a place where wine and hashish mix geographically as well as culturally.

Poets and thinkers in the Muslim world have long debated the virtues and pitfalls of alcohol and marijuana. An epic poem written by Muhammad Ebn Soleman Forbali, a 16th century Turkish poet from Baghdad, portrays a dialectical battle between wine and hashish. The two inequates engage in an allegorical fencing match as the poet describes the euphoric properties of both substances and their consequences, a subject much discussed among Muslim scholars. Forbali viewed wine as the drink of the rich, “while hashish,” he said, “is a friend of the poor; the Dervishes and the men of knowledge.”

Scientists have only recently begun to investigate and understand the critical role that the endocannabinoid system plays in alcohol addiction and various mood disorders.

The struggle between weed and wine continues to unfold in 21st century America, where the alcohol industry funds organizations that seek to maintain marijuana prohibition. Such influence-peddling by Booze, Inc. is not only a blow to the social justice case against a recreational competitor; drug war posturing is also smooth public-relations for liquor companies. The way they manage their image shapes the way the products are perceived: Alcohol is a pivotal factor in many problems, including suicide and accidental deaths, violent crime, drug abuse, work accidents and health costs, and the American medical establishment has spent billions of dollars researching the effects of alcohol on the brain and its functions. The endocannabinoid system plays a key role in alcohol addiction and other mood disorders.

According to several studies, ethanol exposure alters endocannabinoid levels in different regions of the mammalian brain. In a plenary lecture at the 2008 International Cannabinoid Research Society conference, Larry Parsons, Associate Professor at the San Diego-based Scripps Research Institute, discussed findings from his lab on the endocannabinoid levels in the nucleus accumbens of ethanol-exposed rats. The nucleus accumbens is a section of the brain that mediates the pleasurable and reinforcing properties of psychoactive substances. In vivo microdialysis of the nucleus accumbens in ethanol-exposed rats disclosed that the amount of 2-arachidonoylglycerol (2-AG, the most prevalent endocannabinoid in the brain) increased and decreased in direct proportion to the amount of ethanol consumed.

Scientists believe that alcohol has a dose-dependent effect on 2-AG levels in humans as well as rodents. In other words, when a person gets a little tipsy from drinking booze, his or her 2-AG levels rise slightly; when someone gets drunk: a lot of 2-AG sloshes around the brain; and as inebriation fades, 2-AG returns to its normal baseline level.

Parsons and a team of researchers also documented that heroin administration triggers a corresponding rise in anandamide (the other key endocannabinoid) in the rats’ nucleus accumbens, but had no effect on 2-AG levels. Anandamide and 2-AG both activate the all-important CB1 cannabinoid receptor, which is concentrated in the mammalian brain and central nervous system. The CB1 receptor is associated with the spinal reward system and is triggered by THC or synthetic cannabinoid agonists. THC also stimulates CB2 receptor signaling, but this does not result in the euphoric buzz that cannabis is famous for; THC binding to CB1 does the trick.

Parsons’ findings—which were initially reported in the Journal of Neuroscience—raise intriguing questions regarding the causes of alcoholism and drug addiction. Is it possible that the pleasurable effects of alcohol consumption are partly attributable to higher levels of 2-AG and CB1 activity? Why does the endocannabinoid system kick into high gear when a person drinks booze? Do genetic mutations contribute to alcoholic proclivities and skewed endocannabinoid signaling in the brain? Ethanol is metabolized into acetaldehyde, a carcinogen and a mutagen that causes many harmful effects in vital organs. Simply put, alcohol is poison, and science has shown that the basic function of the endocannabinoid system is to protect the body. Shortly after the 2-AG in the nucleus accumbens during ethanol exposure.

High 2-AG levels are also triggered by binge and other traumatic brain injuries, according to a recent article in Neurotoxicology, which concluded that the endocannabinoid system is protective. It can be viewed as part of the body’s “general protective network, working in conjunction with the immune system and various other physiological systems.”

The human brain is a delicate organ, stoutly defended by a thick blood-brain barrier primed to keep foreign substances from penetrating. The endocannabinoid system is a crucial component of the brain’s overall protective apparatus. Parsons put it this way: “Endocannabinoid buffer stress... An increase in endocannabinoid levels indicates the brain is acting as a buffer to physiological and behavioral stress.”

Parsons did not comment on the stress-buffering qualities of phytocannabinoids. In 2009, the journal Neuropsychopharmacology and Teratology presented clinical data indicating that compounds in marijuana helped to “protect the human brain against alcohol-induced damage.”

This study, conducted at the University of California in San Diego, found that adolescents who smoke marijuana may be less susceptible to brain damage from binge drinking.

Five years earlier, researchers at the National Institute of Mental Health demonstrated that cannabinoid (CBD), a significant nonpsychoactive component of marijuana, functioned as an in vivo neuroprotector—in preventing binge ethanol-induced brain injury.” CBD reduced alcoholic-induced cell death in the hippocampus and the entorhinal cortex of the brain in a dose-dependent manner by 60 percent.

Vomiting due to excessive intake of alcohol can be seen as another example of the protective function of the endocannabinoid system, which controls nausea and emesis. Severe vomiting associated with binge drinking is the body’s way of protecting itself by expelling poison. Fifty million Americans, including nearly half of America’s college students, engage in binge drinking, according to a survey by the Harvard School of Public Health. Fifteen million Americans—10 percent of the adult population—are either addicted to or severely debilitated by alcohol.

Whereas acute alcohol exposure increases endocannabinoid levels in the brain, chronic alcohol use results in a systemic decline in endocannabinoid signaling and deficient endocannabinoid baseline levels. Parsons and co-workers report that prolonged ethanol exposure causes “diminished CB1 receptor expression,” less efficient CB1 receptor binding activity and “reduced baseline extracellular 2-AG levels in the amygdala.”

Repeated alcohol consumption also desensitizes and weakens CB1 receptor function in the brain region known as the ventral striatum. Dysfunction of CB1 signaling in the ventral striatum correlates with increased vulnerability to alcohol addiction and suicidal tendencies. Writing in the Journal of Psychiatric Research, Yaradahari Vinod and colleagues proposed that pharmacological agents which “modulate the endocannabinoidergic system” might function might have therapeutic potential in the treatment of alcohol addiction and prevention of suicidal behavior.

Alcohol dependence is linked to down-regulation of 2-AG and CB1 brain receptors.

Long-term alcohol abuse depletes endocannabinoid tone, and this, in turn, has an adverse impact on a plethora of physiological processes that are modulated by the endocannabinoidergic system. The endocannabinoid system interacts with other neurotransmitters (serotonin, dopamine, etc.) involved in the regulation of mood, fear, and impulsive behavior. Endocannabinoid deficiency is associated with a reduced ability or inability to adapt to chronic stress, a systemic dysfunction that becomes more pronounced during alcohol withdrawal. Alcohol dependence is linked to the down-regulation of 2-AG and CB1 brain receptors. Prolonged alcohol exposure induces deficits in the brain’s endocannabinoid signaling, which, in turn, contributes to maladaptive stress coping and a renewed desire for boozing consumption in a self-destructive attempt to boost CB1 receptor activity. The vicious cycle of addiction feeds on itself.

Given that endocannabinoid signaling is implicated in the behavioral and biochemical processes underlying alcohol addiction, some scientists thought that it might be possible to treat alcoholism by blocking the CB1 receptor in order to interrupt the brain’s drug reward pathway. It was a harbored theory that never panned out in the lab. Far from being efficacious CB1 agonists, the administration of a CB1 receptor antagonist would block the brain’s crucial neuroprotective response during alcohol poisoning. From a medical perspective, that would be malpractice.

ACLCOLHOLICS ANONYMOUS defines recovery in terms of abstinence from all illicit substances, including cannabis.
Enhancing Endocannabinoid Tone

Researchers focusing on alcoholism are currently exploring the possibility of “enhancing endocannabinoid tone” by manipulating the enzymes that control 2-AG and anandamide metabolism. One approach relies on URB-597, an experimental drug that inhibits fatty acid amide hydrolase (FAAH), an enzyme that breaks down endocannabinoids. Forrestalling the enzymatic degradation of 2-AG and anandamide raises endocannabinoid levels in the brain. FAAH-inhibitors indirectly bolster CB1 receptor signaling.

Parson’s rat-brain-microdialysis research suggests that FAAH-inhibitors, by facilitating increased CB1 activity, can reduce anxiety-like behavior associated with alcohol dependence. FAAH inhibitors have also demonstrated therapeutic benefits in animal models of other severe disorders, including neuropathic pain, neural degenerative conditions, epileptic seizures, hypertension, depression, and inflammatory bowel disease, as well as against the proliferation and migration of cancer cells, according to Stephan Petrosino and Vincenzo Di Marzio at the University of Naples.1

Additional studies indicate that genetic mutations may contribute to the dysregulation of endocannabinoid signaling.10 For example, 99% of people who engage in problem alcohol consumption carry a “polymorphism” in their FAAH gene. Scientists have linked a prevalent genetic condition (so-called “single nucleotide polymorphism”) to increased alcohol consumption among the stressed-out masses. After medical marijuana was legalized in California in 1996, Dr. Tod Mikuriya and several like-minded physicians successfully treated hundreds of alcoholic patients who got their lives back after switching to pot. Parson’s brain research implicates FAAH inhibitors as a harm reduction strategy for treating alcoholism. But the idea of substituting marijuana for alcohol and other addictive substances is still strictly taboo in NIDA-contracted scientific laboratories, where synthetic endocannabinoids, such as THC, are used as a research tool.8

To assess the extent to which medical marijuana patients are using the herb as a replacement for alcohol, all participants reported cannabis substitution as very effective or effective,” said Marco Armentano, Senior Staff Scientist, NORML. “When addressing the efficacy of cannabis as a substitute for alcohol, all participants reported cannabis substitution as very effective or effective.” Armentano noted. Twenty-six percent of those surveyed said they used marijuana as a substitute for alcohol.8

Some cannabis dispensaries now sponsor recovery-oriented support groups. But those who use cannabis to reduce the craving for alcohol and/or hard drugs must practice less than rigorous honesty if they attend meetings. Some cannabis dispensaries now support recovery-oriented support groups. Many references in the medical literature support the use of marijuana in the treatment of drug and alcohol addiction.4

References

1. Cocaine had no measurable effect on endocannabinoid levels in the nucleus accumbens. 
9. Timo D. Mueller, et all, “Mutation of the FAAH gene encoding the endocannabinoid inactivating enzyme FAAH is often found in people who engage in problem alcohol and drug use. This same FAAH gene polymorphism, according to German researchers, is often present in patients with obesity and irritable bowel disease.”
10. Of course, there is another way to enhance CB1 signaling and adjust enzymatic processes — one could smoke, vaporize or eat cannabis, a natural, non-toxic herb, and thereby influence gene expression. THC, as noted earlier, activates both the CB1 and CB2 receptors. And CBD, the second most prominent cannabinoid in marijuana, inhibits FAAH. What’s more, THC and CBD work best in tandem, synergistically, so to speak, along with dozens of other phytocannabinoids, terpenes and flavonoids that are found in cannabis. Endocannabinoid deficiency? If alcoholism is an endocannabinoid deficiency syndrome, then it makes perfect sense that people might successfully wean themselves from booze by smoking marijuana, which triggers to keep pot illegal; rather it is the reason we must make it legal,” assert the authors of Marijuana is SAFER — so why are we driving people to drink.

Paul Armentano, Steve Fox and Mason Tvert are veteran reform advocates who have hosted their arguments against pot prohibition and the legal double standards that privilege wine over weed. Now they have compiled them in J’Accuse-like manifesto. The bottom line: if legalizing marijuana results in a decline in alcohol use, that’s a good thing from a public health perspective. And if it results in the wider use of marijuana, with its demonstrable neuroprotective properties, so much the better.

Many references in the medical literature support the use of marijuana in the treatment of drug and alcohol addiction.
